WHY ENCLAVE

What makes agents useful makes them hard to govern

Autonomy is the value

Useful agents run commands, install packages, and edit files unasked.

Your host is the blast radius

Every credential is unlocked on disk: SSH keys, cloud tokens, secrets, and full internet access.

Prompt injection is an attack path

A poisoned README or web page turns the agent into someone else's tool.

Hard to account for

Every agent logs differently. Across agents, nobody can say what was reached, or under which policy.

© 2026 EclipseSource · Philip Langer

WHAT IS ENCLAVE

Don’t control the agent. Control the sandbox it runs in.

Agents come and go. Policies, compliance rules and reporting should stay.

Full autonomy, inside the box

The agent runs and installs whatever it needs, with no permission prompts.

Only the project is visible

No SSH keys, no home directory, and only allowlisted services.

Enforced outside the agent

A poisoned README can trick the agent, but it cannot change the sandbox's rules.

One policy, any agent, on record

The organisation sets the rules once. The sandbox enforces and logs them at the boundary.

WHY THE ECLIPSE FOUNDATION

The part you trust most needs a neutral home

ECLIPSE FOUNDATION

- **Neutral and lasting.** No single vendor controls it, not even EclipseSource, under a foundation industries have relied on for decades.
- **Open and inspectable.** Auditors can read the code that enforces the policy.
- **Sovereign AI for industry.** Part of the Eclipse Foundation's AI landscape, next to the AI Registry and more.

In contrast, the recent wave of agent sandboxes

Tied to one vendor

Bound to a model service, harness or infrastructure. Controlled by one company.

Open, but fragile

Run by an individual or a fragmented community. A risky dependency for a company.

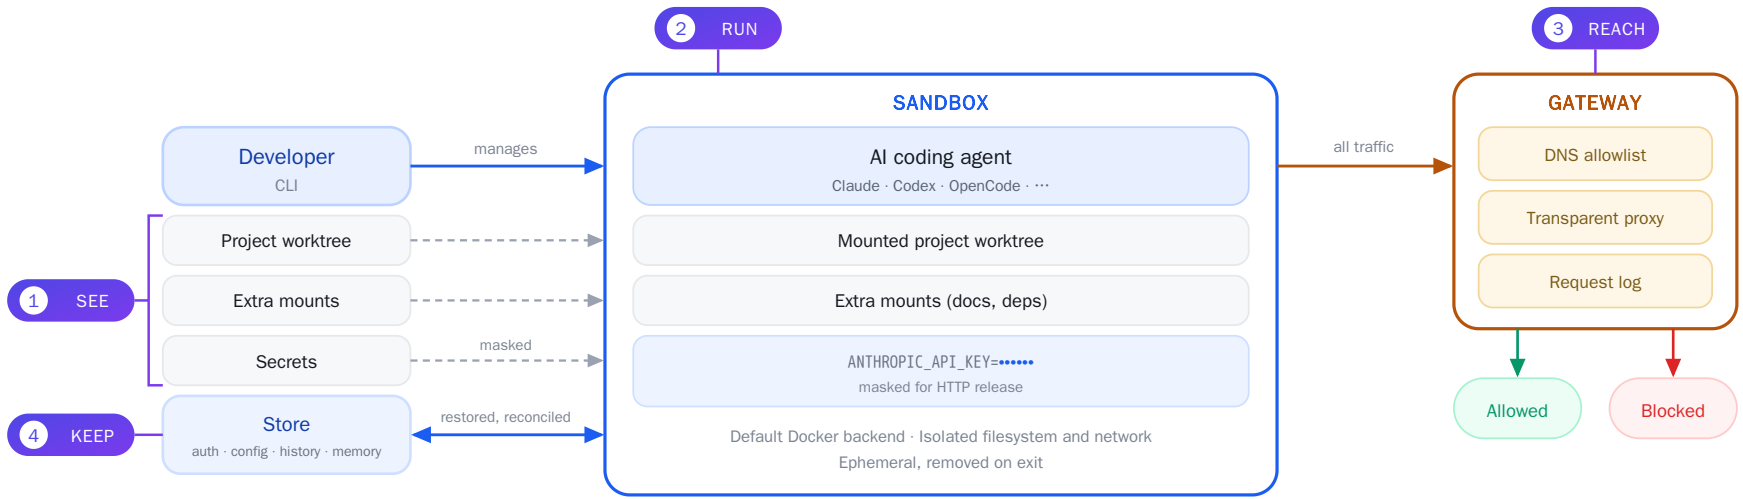

An Eclipse Foundation project, MIT licensed, developed in the open.

WHAT IS ENCLAVE

Anatomy of a session

Every session answers four questions. Each answer is a policy the organisation sets.

1 · SEE
What is visible?

2 · RUN
What is executed?

3 · REACH
What can the agent talk to?

4 · KEEP
What survives the sandbox?

EclipseSource

LIVE DEMO 1

No friction to be safe

```
$ enclave
```

Run it in any project directory.
Enclave does the rest.

- Prepares an isolated environment with the agent installed
- Mounts your project, and nothing else from your home
- Starts the network gateway with a domain allowlist; everything else is blocked and logged
- Persists auth, config and history, so you log in only once
- Starts the agent with full autonomy, no permission prompts

© 2026 EclipseSource · Philip Langer

EVIDENCE

LIVE DEMO 2

Every network decision is on record

```
# on the host, while the agent works
$ enclave network log -f --tool codex --since session

 SESSION  core-codex  2026-10-27 14:31:02

 14:31:40  ✗  dns  eclipsesource.com  nxdomain
```

Stamped per session, kept on disk per project and agent after the session ends.

What it is, and what it is not

A record of decisions. Which destination, when, allowed or blocked, and why.

Not a content log. What the agent tried to send is not recorded.

One entry per connection by default. A detailed mode records every request.

EVIDENCE

LIVE DEMO 3 · PROOF OF CONCEPT

What a session leaves behind

Network log	Every allowed and blocked destination, per session.
Configuration	The settings in effect, and where each one came from: built-in default, user, project, or command line.
Extensions	Which agents, policies and skills were installed, from which repository, at which exact version.
Environment	The sandbox is built from declared specs and identified by a fingerprint of their exact content.
The work	Commits under the developer's git identity, and the agent's conversation history, kept per project.

All exportable as JSON. Today: local files only, not signed, not collected centrally, no retention policy.

POLICY AS CODE

LIVE DEMO 4 · PROOF OF CONCEPT

Organisation policies ship as extensions

```
# your organisation's policy, in a git repository
acme/enclave-policy/
  features/acme-policy/
    spec.yaml      allowed domains, credentials
    skills/        rules every agent follows
    commands/host/ e.g. a report command

# every developer, once
$ enclave features add acme/enclave-policy

# roll out the next approved version
$ enclave features update
```

- **Written once, for every agent.** Claude, Codex, Copilot and others run under the same rules.
- **Reviewed like code.** Policies live in git, with history and approval.
- **Traceable.** Each install records its source repository and exact commit.
- **Shared across teams.** Organisation-wide, then refined per team or project.

LET'S WORK ON THIS TOGETHER

We need your expertise

Which policies, and who owns them?

Which use cases need which rules, who defines them, and how do they reach every developer? When must a policy be locked?

Standardised evidence

Which session records would meet the CRA, the AI Act or your own audits? Could we agree on one format, signed and kept the same way everywhere?

What tooling would you use?

You saw two prototypes: a session audit report and a policy editor. What would fit your processes?

How far should the trail reach?

From session to commit, SBOM and release: should a shipped change record which agent and policy produced it?

Frontier efficiency, without the compromise.

Agents come and go. The sandbox stays.

```
$ enclave
```

Pre-release available now for Linux, macOS and WSL2.
Containerization options: Docker, rootless podman, or qemu microvms (experimental)

BACKUP

On the roadmap

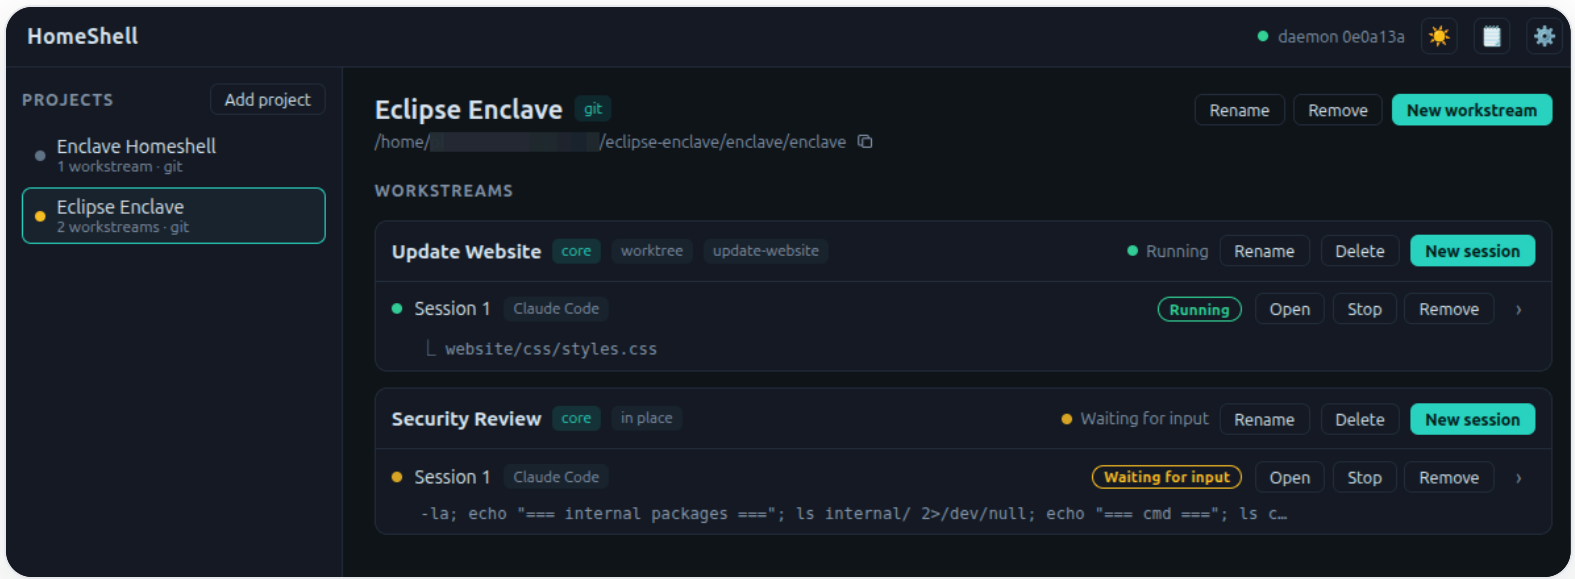

AI Registry	IN PROGRESS	Resolve extensions through the Eclipse Foundation's AI Registry, so teams govern which agents, skills and MCP servers a session may use.
Audit Controls	EXPLORING	Work out, with people who know the rules, which session records can support CRA and AI Act documentation.
Guardian sidecar	EXPLORING	Watch what the agent does inside the box, not only what leaves it.
